(Dated: September 30, 2015)

Flavour changing neutral scalar interactions are a standard feature of generic multi Higgs models. These are constrained by mixing in the neutral meson systems. We consider situations where there are natural cancelations in such contributions. In particular, when the spin 0 particle has both scalar and pseudoscalar couplings, one may have a *self-cancelation*. We illustrate one such partial cancelation with BGL models. We also inquire whether the flavour changing quark interactions can lead to new production mechanisms for a neutral scalar at LHC.

I. INTRODUCTION

The recent discovery of a scalar particle by ATLAS [1] and CMS [2] leaves a fundamental question unanswered: given that a fundamental scalar exists, how many fundamental scalars are there in Nature? Indeed, within an $SU(2)_L \times U(1)_Y$ gauge theory, the number of gauge bosons is fixed. In addition, measurements of the invisible width of the Z boson at LEP [3] have fixed the number of fermion families to be three (below $M_Z/2$). So, only the number of spin zero particles remains to be determined.

The most natural simple extension of the standard model (SM) is the two Higgs doublet model (2HDM) – for a review, see for example [4, 5]. This model is interesting in itself, but also as a toy model for a wide number of features that could appear in other more complicated settings: among others, it includes the need to restrict the parameter space, such that the vacuum does not violate charge; the appearance of extra scalar and pseudoscalar particles; the possibility that CP is violated in the scalar sector, either explicitly or spontaneously; the existence of charged scalars which, like the $W^\pm$, would change flavour; and the possibility that there are flavour changing neutral scalar interactions (FCNSI). In this article we explore the last feature, considering two consequences. If there exists a scalar with FCNSI, this will have a twofold effect. On the one hand, it could conceivably be produced at the LHC through quark level interactions such as $u\bar{c}$, $d\bar{s}$, $\bar{d}s$, etc... On the other hand, these production mechanisms must be constrained by the fact that the same couplings could originate FCNSI in neutral meson systems, such as $K^0 - \overline{K}^0$ or $B^0 - \overline{B}^0$, which we denote generically by $P^0 - \overline{P}^0$.

Flavour changing neutral interactions, such as $K^0 - \overline{K}^0$ and $K^0 \to \mu^+\mu^-$ have played a crucial role in the history of Physics. For example, CP violation was first seen in the $K^0 - \overline{K}^0$ system [6], while the charm quark was invented to curtail a large contribution for $K^0 \to \mu^+\mu^-$ from the box diagram with the up quark [7]. More recently, the first evidence of CP violation outside of the kaon system was found by the Babar and Belle experiments [8, 9], showing that it arises from a large (not small) parameter, and the first evidence of $B_{d,\,s} \to \mu^+\mu^-$ has been found [10].

Bounds on $P^0 - \overline{P^0}$ mixing lead to constraints on the coupling $c_{Sq_2q_1}$ of the scalar S with quarks q_1 and q_2 that scale linearly with the mass m_S of S:

$$c_{Sq_2q_1} \propto m_S. \tag{1}$$

Limits also arise from bounds such as $B_s \to \mu^+\mu^-$, scaling quadratically as

$$c_{Sq_2q_1} \propto \frac{1}{c_{S\mu\mu}}\, m_S^2. \tag{2}$$

*E-mail: nebot@cftp.ist.utl.pt
†E-mail: jpsilva@cftp.ist.utl.pt

Generically, Eq. (2) provides a looser bound than Eq. (1) for a sufficiently large m_S. Moreover, Eq. (2) involves the coupling $c_{S\mu\mu}$ of S with $\mu^+\mu^-$, which might even be zero if the scalar S has no overlap with the (would-be) SM Higgs field $H^{\rm sm}$. In both cases, scalars with larger masses have a looser constraint on $c_{Sq_2q_1}$ and, thus, could conceivably be produced at LHC via $pp \to q_2q_1 \to S$. This analysis points to a (further) interesting complementary feature between Flavour Physics, such as would be pursued at a Super B-factory, and the scalar search to be continued at LHC's Run2. Of fundamental interest is the question: how would $pp \to q_2q_1 \to S$ compare with the glue-glue production mechanism $pp \to gg \to S$?

In Section II, we introduce the mechanism of self-cancelation, possible when there are both scalar and pseudoscalar couplings. This is then discussed in increasingly particular cases of the two most general 2HDM, the CP conserving 2HDM, and the BGL models. In Section III we turn to the possibility that the scalar is produced at the LHC through FCNSI couplings, and we conclude in section IV. For completeness, the appendix contains formulas for FCNSI effects obtained for the most general Lagrangian, other than those derived in the main text.

II. SELF-CANCELATION IN NEUTRAL MESON MIXING

A. Generic scalar contribution

Let us consider a spin 0 particle S interacting with two quarks q_i and q_j according to

$$-\mathcal{L}_Y = S\left\{\bar{q}_j\left(a_{\bar{j}i} + ib_{\bar{j}i}\gamma_5\right)q_i + \bar{q}_i\left(a^*_{\bar{j}i} + ib^*_{\bar{j}i}\gamma_5\right)q_j\right\} + \cdots \tag{3}$$

No sum on i and j is implied. If $q_j = q_i$, then a and b are real; otherwise, they are complex. In writing Eq. (3) we have already used hermiticity in the form

$$a_{\bar{i}j} = a^*_{\bar{j}i}, \qquad b_{\bar{i}j} = b^*_{\bar{j}i}. \tag{4}$$

If all b_{ij} (a_{ij}) were zero, then S would be a pure scalar (pseudoscalar). Otherwise, S will be a mixture of scalar and pseudoscalar, and there is P violation. It is interesting to note that there are still viable models in which the 125 GeV scalar found at LHC has a pure scalar couplings to the up quarks, while it has a pure pseudoscalar couplings to the down quarks [11].

We are interested in the neutral meson systems constituted by $P^0 \sim \bar{q}_jq_i$ and $\overline{P^0} \sim \bar{q}_iq_j$. $\mathcal{L}_Y$ contributes to an effective Hamiltonian, mediating the mixing [12]

$$\begin{aligned} M_{21} &= \langle\overline{P^0}\,|\mathcal{H}_{\rm eff}|\,P^0\rangle. \\ &= \frac{f_P^2\,m_P}{24\,m_S^2}\left[a^2_{\bar{j}i}K_a^P + b^2_{\bar{j}i}K_b^P\right]. \end{aligned} \tag{5}$$

We denote by m_P, Δm_P, and f_P the average mass, the mass difference, and the form factor of the $P^0 - \overline{P^0}$ system, respectively. Under reasonable approximations [12],

$$\Delta m_P = 2|M_{21}|. \tag{6}$$

In the vacuum insertion approximation, discussed in detail in appendix C of Ref. [12][1], we find

$$\begin{aligned} K_a^P &= 1 + \frac{m_P^2}{(m_{q_j} + m_{q_i})^2}, \\ K_b^P &= 1 + 11\,\frac{m_P^2}{(m_{q_j} + m_{q_i})^2}, \end{aligned} \tag{7}$$

for the scalar and pseudoscalar operators, respectively.

Although our main points do not depend on the exact values of K_a^P and K_b^P, we show in Table I a rough estimate based on the vacuum insertion approximation of Eq. (7) and the relevant input parameters. The quark masses are

[1] Notice that there are a few sign misprints in the hardcover edition of [12], corrected both in the paperback edition and here.

Meson system	K^0–$\bar{K}^0$	B_d^0–$\bar{B}_d^0$	B_s^0–$\bar{B}_s^0$	D^0–$\bar{D}^0$
η	1.0	0.1	0.1	1.0
Δm_P	3.484×10^{-15}	3.337×10^{-13}	1.17×10^{-11}	6.58×10^{-15}
m_P	0.497	5.28	5.37	1.86

m_{q_1}, m_{q_2}	m_d, m_s	m_d, m_b	m_s, m_b	m_u, m_c
K_a^P	25.8	2.58	2.56	3.12
K_b^P	273.8	18.3	18.2	24.3

TABLE I: Meson mixing input; Δm_P, M_P, f_P, m_q in GeV. Taken from Ref. [17].

taken (in GeV) as $m_u = 0.0023$, $m_d = 0.0048$, $m_s = 0.095$, $m_c = 1.275$, and $m_b = 4.2$ [17]. We notice that the pseudoscalar matrix elements K_b^p are always larger than their scalar counterparts K_a^p. For example, in the B systems, we get $K_b^P/K_a^P \sim 7$ in the vacuum insertion approximation. It is interesting to compare with the values obtained from lattice. For instances, we find

$$\begin{aligned} f_{B_q}^2 K_a^{B_q} &= -5 f_{B_q}^2 B_{B_q}^{(2)} + 6 f_{B_q}^2 B_{B_q}^{(4)}, \\ f_{B_q}^2 K_b^{B_q} &= 5 f_{B_q}^2 B_{B_q}^{(2)} + 6 f_{B_q}^2 B_{B_q}^{(4)}, \end{aligned} \tag{8}$$

where the right-hand side involves the quantities introduced in Ref. [18][2]. In particular, $B_{B_q}^{(2)}$ $(q = d, s)$ is the bag parameter common to the operators $\mathcal{O}_2 = (\bar{b}\gamma_L q)^2$ and $\tilde{\mathcal{O}}_2 = (\bar{b}\gamma_R q)^2$, with $\gamma_{L,R} = (1 \mp \gamma_5)/2$, while $B_{B_q}^{(4)}$ $(q = d, s)$ is the bag parameter of the operator $\mathcal{O}_4 = (\bar{b}\gamma_L q)(\bar{b}\gamma_R q)$. The results obtained from lattice differ from those in the vacuum insertion approximation by at most a factor of three. Of crucial importance is the ratio $K_b^{B_q}/K_a^{B_q} \sim 3$ obtained from lattice. The fact that the ratio obtained using the lattice results of [18] is closer to unity than that obtained in the vacuum insertion approximation will be of interest in the following.

Next we highlight one of the main points in this work. In Eq. (5) the scalar and pseudoscalar components appear independently; there are terms in $a_{\bar{j}i}^2$ and $b_{\bar{j}i}^2$, but no term in $a_{\bar{j}i} b_{\bar{j}i}$. One would say that they do not interfere. But, because $a_{\bar{j}i}^2$ and $b_{\bar{j}i}^2$ are complex, Eq. (5) shows the very interesting feature that the two terms can cancel each other. And, as we will illustrate below, there are generic classes of models in which they could easily arise with the opposite sign. This has the result that the scalar contribution of a spin zero particle may cancel the pseudoscalar contribution of that *same* spin zero particle. There are known instances where the contribution of some scalar cancels the contribution of some other scalar. This occurs, for instances, in the scalar contributions to the electric dipole moment of the electron in CP violating two Higgs doublet models, when in the decoupling limit [13]. But the feature present in Eq. (5) is something else. It is the two components of a single scalar that may cancel each other. We denote this effect by "self-cancelation". As far as we know, this feature hasn't been properly appreciated before, especially in the context of its implications for the LHC.

B. Self-cancelation in the most general two Higgs doublet model

The Yukawa interactions of quarks in the two Higgs doublet model (2HDM) may be written as

$$-\mathcal{L}_Y = \bar{q}_L(\Gamma_1 \Phi_1 + \Gamma_2 \Phi_2) n_R + \bar{q}_L(\Delta_1 \tilde{\Phi}_1 + \Delta_2 \tilde{\Phi}_2) p_R + \text{h.c.}, \tag{9}$$

where Φ_a $(a = 1, 2)$ are the Higgs doublets, $q_L = (p_L, n_L)^T$ is a vector in the 3-dimensional family space of left-handed doublets, and n_R and p_R are 3-dimensional vectors in the right-handed spaces of charge $-1/3$ and $+2/3$ quarks, respectively. The complex 3×3 matrices Γ_1, Γ_2, Δ_1, and Δ_2 contain the Yukawa couplings.

After spontaneous symmetry breaking, the fields acquire the vacuum expectation values (vevs) $v_1/\sqrt{2}$ and $v_2/\sqrt{2}$. In general, v_1 and v_2 are complex, but one may, without loss of generality, choose a basis where v_1 is real and

[2] Notice that our conventions for matrix elements differs from those in Ref. [18] by a minus sign and by $1/(2m_B)$. Of course, physical results are the same and, when all is properly taken into account, one obtains Eqs. (8).

$v_2 = |v_2|e^{i\delta}$. It is convenient to perform a unitary transformation into the Higgs basis $\{H_1, H_2\}$ through [19, 20]

$$\begin{pmatrix} H_1 \\ H_2 \end{pmatrix} = U^\dagger \begin{pmatrix} \Phi_1 \\ \Phi_2 \end{pmatrix}, \tag{10}$$

where

$$U^\dagger = \frac{1}{v}\,\mathrm{diag}\left(1, e^{i\chi}\right) \begin{pmatrix} v_1^* & v_2^* \\ -v_2 & v_1 \end{pmatrix}, \tag{11}$$

is unitary, and $v = \sqrt{v_1^2 + v_2^2} = (\sqrt{2}G_F)^{-1/2}$. As is clear from Eq. (11), all the vev is now in H_1. And, since H_2 has no vev, its phase can be altered at will. We will choose $\chi = 0$, Ref. [21] has $\chi = -\delta + \pi$. We may write

$$\begin{aligned} H_1 &= \begin{bmatrix} G^+ \\ (v + H^{\rm sm} + iG^0)/\sqrt{2} \end{bmatrix}, \\ H_2 &= \begin{bmatrix} H^+ \\ (R + iI)/\sqrt{2} \end{bmatrix}, \end{aligned} \tag{12}$$

where G^+ and G^0 are the would-be Goldstone bosons and H^+ is the charged scalar. $H^{\rm sm}$, R and I are neutral fields. The Yukawa couplings in the Higgs basis are given by $\Gamma_a^H = \Gamma_b U_{ba}$, $\Delta_a^H = \Delta_b U_{ba}^*$. Since only H_1 has a vev, the quark masses arise solely from Γ_1^H and Δ_1^H as

$$\begin{aligned} \frac{v}{\sqrt{2}} U_{d_L}^\dagger \Gamma_1^H U_{d_R} &= D_d = \mathrm{diag}(m_d, m_s, m_b), \\ \frac{v}{\sqrt{2}} U_{u_L}^\dagger \Delta_1^H U_{u_R} &= D_u = \mathrm{diag}(m_u, m_c, m_t), \end{aligned} \tag{13}$$

where the transformations U_α with $\alpha = d_L, d_R, u_L, u_R$ bring the quarks into their mass basis. The couplings to H_2 become

$$\begin{aligned} \frac{v}{\sqrt{2}} U_{d_L}^\dagger \Gamma_2^H U_{d_R} &= N_d\ , \\ \frac{v}{\sqrt{2}} U_{u_L}^\dagger \Delta_2^H U_{u_R} &= N_u\ , \end{aligned} \tag{14}$$

and the Yukawa lagrangian becomes

$$-\frac{v}{\sqrt{2}}\mathcal{L}_Y = (\bar{u}_L V,\ \bar{d}_L)(D_d H_1 + N_d H_2)\ d_R + \ (\bar{u}_L,\ \bar{d}_L V^\dagger)(D_u \tilde{H}_1 + N_u \tilde{H}_2)\ u_R + \ h.c.\ , \tag{15}$$

where $V = U_{u_L}^\dagger U_{d_L}$ is the CKM matrix. In general, N_d and N_u are not diagonal and, thus, responsible for the FCNSI involving R and I. Notice that $H^{\rm sm}$ couples to the quarks proportionally to their masses, as would the SM Higgs particle. But, in general, $H^{\rm sm}$ is not a mass eigenstate.

If $v_1 v_2 \neq 0$, $H^{\rm sm}$ and R are guaranteed not to be mass eigenstates and, if there is CP violation in the pure scalar sector, then I is also not a mass eigenstate. They mix through

$$\begin{pmatrix} H^{\rm sm} \\ R \\ I \end{pmatrix} = T \begin{pmatrix} S_1 \\ S_2 \\ S_3 \end{pmatrix}, \tag{16}$$

into the S_k $(k = 1, 2, 3)$ mass eigenstates corresponding to the three neutral spin 0 particles. Using Eqs. (15) and (16), we can finally write the Yukawa lagrangian of the neutral scalar fields as

$$-\mathcal{L}_Y = \sum_{k=1}^{3} S_k\ \left\{\bar{d}\ \left[A^{d,k} + i\,\gamma_5\,B^{u,k}\right]\ d + \bar{u}\ \left[A^{u,k} + i\,\gamma_5\,B^{u,k}\right]\ u\right\}, \tag{17}$$

where

$$\begin{aligned} v\,A^{d,k} &= T_{1k}\,D_d + T_{2k}\,X_+^d + i\,T_{3k}\,X_-^d, \\ v\,B^{d,k} &= -i\,T_{2k}\,X_-^d + T_{3k}\,X_+^d, \\ v\,A^{u,k} &= T_{1k}\,D_u + T_{2k}\,X_+^u - i\,T_{3k}\,X_-^u, \\ v\,B^{u,k} &= -i\,T_{2k}\,X_-^u - T_{3k}\,X_+^u, \end{aligned} \tag{18}$$

and

$$X_\pm^\alpha = \frac{N_\alpha \pm N_\alpha^\dagger}{2}, \tag{19}$$

for $\alpha = u, d$. The down type couplings agree with those found in Eqs. (22.73)-(22.74) of [12]. Notice that the matrices $A^{\alpha,k}$ and $B^{\alpha,k}$ are hermitian, as needed for a hermitian lagrangian.

We may now calculate the contribution to the P^0–$\bar{P}^0$ mixing matrix element M_{21} in Eq. (5) as

$$\frac{24}{f_P^2 m_P}\; M_{12}^k = \frac{1}{m_{S_k}^2}\left[\left(a_{\bar{j}i}^k\right)^2 K_a^P + \left(b_{\bar{j}i}^k\right)^2 K_b^P\right], \tag{20}$$

where

$$\begin{aligned} v\,a_{\bar{j}i}^k &= \left(A^{\alpha,k}\right)_{\bar{j}i}, \\ v\,b_{\bar{j}i}^k &= \left(B^{\alpha,k}\right)_{\bar{j}i} \end{aligned} \tag{21}$$

and $\alpha = d$ for the K, B_d, and B_s systems, while $\alpha = u$ for the D system.

C. Self-cancelation in a CP conserving pure scalar sector

Although it may seem counterintuitive, one can have a spin 0 state which arises out of a CP conserving Higgs potential, but which, nevertheless, couples with quarks through both scalar and pseudoscalar components. To illustrate this mechanism, let us consider a model which is CP conserving in its pure scalar sector. By this we mean that all couplings in the Higgs potential are real and that both vevs are real. One may write

$$\begin{aligned} v_1 &= v\,c_\beta, \\ v_2 &= v\,s_\beta, \end{aligned} \tag{22}$$

implying that $t_\beta = v_2/v_1$, where, thenceforth, c_θ, s_θ, and t_θ represent the cosine, the sine, and the tangent of some given angle θ, respectively. In such cases, and continuing to consider only the scalar sector, there is one CP odd state ($A \equiv I$), and it is common to define the lighter (h) and heavier (H) CP even states by [22]

$$\begin{aligned} \begin{pmatrix} H \\ h \end{pmatrix} &= \begin{pmatrix} c_\alpha & s_\alpha \\ -s_\alpha & c_\alpha \end{pmatrix} \begin{pmatrix} \rho_1 \\ \rho_2 \end{pmatrix} \\ &= \begin{pmatrix} c_\alpha & s_\alpha \\ -s_\alpha & c_\alpha \end{pmatrix} \begin{pmatrix} c_\beta & -s_\beta \\ -s_\beta & c_\beta \end{pmatrix} \begin{pmatrix} H^{\rm sm} \\ R \end{pmatrix} = \begin{pmatrix} c_{\alpha-\beta} & s_{\alpha-\beta} \\ -s_{\alpha-\beta} & c_{\alpha-\beta} \end{pmatrix} \begin{pmatrix} H^{\rm sm} \\ R \end{pmatrix}, \end{aligned} \tag{23}$$

where $\mathrm{Re}\Phi_a^0 = (\rho_a + v_a)/\sqrt{2}$ $(a = 1, 2)$, and in going to the second line, we have used Eqs. (10), (11), and (22). In this case, Eq. (16) becomes

$$\begin{pmatrix} H^{\rm sm} \\ R \\ I \end{pmatrix} = \begin{pmatrix} c_{\alpha-\beta} & -s_{\alpha-\beta} & 0 \\ s_{\alpha-\beta} & c_{\alpha-\beta} & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} H \\ h \\ A \end{pmatrix}. \tag{24}$$

Thus, the scalar and pseudoscalar couplings of each mass eigenstate to the down type quarks become:

$$\begin{aligned} v\,A^{d,H} &= c_{\alpha-\beta}\,D_d + s_{\alpha-\beta}\,X_+^d, \\ v\,B^{d,H} &= -i\,s_{\alpha-\beta}\,X_-^d, \\ v\,A^{d,h} &= -s_{\alpha-\beta}\,D_d + c_{\alpha-\beta}\,X_+^d, \\ v\,B^{d,h} &= -i\,c_{\alpha-\beta}\,X_-^d, \\ v\,A^{d,A} &= i\,X_-^d, \\ v\,B^{d,A} &= X_+^d. \end{aligned} \tag{25}$$

Similarly, for the up type quarks we find

$$\begin{aligned} v\,A^{u,H} &= c_{\alpha-\beta}\,D_u + s_{\alpha-\beta}\,X_+^u, \\ v\,B^{u,H} &= -i\,s_{\alpha-\beta}\,X_-^u, \\ v\,A^{u,h} &= -s_{\alpha-\beta}\,D_u + c_{\alpha-\beta}\,X_+^u, \\ v\,B^{u,h} &= -i\,c_{\alpha-\beta}\,X_-^u, \\ v\,A^{u,A} &= -i\,X_-^u, \\ v\,B^{u,A} &= -X_+^u. \end{aligned} \tag{26}$$

Let us concentrate on the neutral meson systems with down-type quarks. Since D_d is diagonal, the relevant coefficients are simplified into those listed in Table II. Let us assume that the corresponding elements in X_+^d and X_-^d

scalar	$v^2\,\left(a_{\bar{j}i}^k\right)^2$	$v^2\,\left(b_{\bar{j}i}^k\right)^2$
H	$s_{\alpha-\beta}^2\left(X_+^d\right)_{\bar{j}i}^2$	$-s_{\alpha-\beta}^2\left(X_-^d\right)_{\bar{j}i}^2$
h	$c_{\alpha-\beta}^2\left(X_+^d\right)_{\bar{j}i}^2$	$-c_{\alpha-\beta}^2\left(X_-^d\right)_{\bar{j}i}^2$
A	$-\left(X_-^d\right)_{\bar{j}i}^2$	$\left(X_+^d\right)_{\bar{j}i}^2$

TABLE II: Scalar and pseudoscalar couplings present in 2HDMs with CP conservation in the Higgs potential and in the vevs.

have the same phase. As we will illustrate in Section II E, this is a rather common feature. In that case, the opposite signs appearing in the two columns of Table II imply a cancelation. Indeed, for each scalar particle (for each row in Table II), the $\left(a_{\bar{j}i}^k\right)^2$ contribution has the opposite sign to the $\left(b_{\bar{j}i}^k\right)^2$ contribution. This means that the scalar contribution of one spin 0 particle tends to cancel the pseudoscalar contribution of the *same* spin 0 particle[3].

In getting to Table II nothing was assumed besides CP conservation in the Higgs potential and in the vevs. So, the self-cancelation is a generic feature of these 2HDMs. For the self-cancelation to be complete in Eq. (21) one would need

$$\left(X_+^d\right)_{\bar{j}i}^2\;\; K_a^P \sim \left(X_-^d\right)_{\bar{j}i}^2\;\; K_b^P \tag{27}$$

for h and H, while

$$\left(X_-^d\right)_{\bar{j}i}^2\;\; K_a^P \sim \left(X_+^d\right)_{\bar{j}i}^2\;\; K_b^P \tag{28}$$

would be needed for A. If all masses were of the same order, then a cancelation in H and h would imply a non-cancelation in A, and vice-versa.

But there are other possibilities. Recall that $s_{\alpha-\beta}$ controls the coupling of h to the vector bosons ZZ and W^+W^-. If h coincides with the scalar found a LHC, then $s_{\alpha-\beta}$ should not differ much from unity. In that case, the $c_{\alpha-\beta}^2$ factors in Table II curtail the h contributions. Then, one could have a self-cancelation in H and a small A contribution due to $m_A \gg m_H$, or vice-versa.

[3] Notice that this is completely unrelated to any further cancelation which might occur between *different* spin 0 particles. For example, if one takes $m_H = m_h = m_A$ and $\left(X_+^d\right)_{\bar{j}i}^2 = \left(X_-^d\right)_{\bar{j}i}^2$, then the H, h, and A contributions cancel exactly.

D. A conundrum of scalar-pseudoscalar mixing with a CP conserving Higgs potential

In Section II C we considered models where there is CP conservation in the Higgs potential, which remains unbroken by the vevs. In such cases, at tree level, the spin 0 states are eigenstates of CP defined in the pure scalar sector: H and h are CP even, while A is CP odd. Nevertheless, each spin 0 particle couples to quarks as in Eq. (3), meaning that it has both scalar (a_{ji}) and pseudoscalar (b_{ji}) couplings to quarks. Is there a contradiction? No! There is no contradiction.

Let us start by considering the diagonal couplings. The point is that there is no CP violation in the pure scalar sector. This means that the parameters of the Higgs potential are real and so are the vevs. As a result, the tree level mass matrix for the neutral scalars is block diagonal and there is no CP violation in the pure scalar sector. This can be seen in a basis independent fashion through the basis invariant measures of CPV introduced by Lavoura and Silva [19]. They all vanish. So, where does the CP violation in $a_{ii}b_{ii} \neq 0$ come from? As is obvious from Eq. (3), it comes from the couplings with quarks; from the N_d and N_u matrices in Eqs. (14), originating in the complex Yukawa matrices and driving the FCNSI. Botella and Silva [20] have developed basis invariant measures of CP violation which measure precisely this type of CP violation arising from the beating of the scalar sector against the Yukawa sector. And the relation between these invariants and Eq. (3) is discussed in sections 22.9.2-22.10 of Ref. [12]. What does not seem to have been appreciate then is that such effect can lead to self-cancelations, thus hiding potentially interesting FCNSI phenomena. In this respect, we stress the results found so far. The assumption that there are no cancelations is far from natural. It turns out that reasonable models lead naturally to (at least some degree of) cancelations.

Let us now look at non diagonal couplings. Once in the scalar and quark mass basis, the most general CP transformations can be written as [12]

$$\begin{aligned}
(\mathcal{CP})\ q_i\ (\mathcal{CP})^\dagger &= e^{i\xi_i}\gamma^0 C\bar{q}_i^T, \\
(\mathcal{CP})\ \bar{q}_j\ (\mathcal{CP})^\dagger &= -e^{-i\xi_j} q_j^T C^{-1}\gamma^0, \\
(\mathcal{CP})\ S\ (\mathcal{CP})^\dagger &= \eta_S\, S,
\end{aligned} \tag{29}$$

where ξ are spurious phases brought about by the CP transformation [12], and we have considered only signs $\eta_S = \pm 1$ for the scalar field. These can be combined into

$$\begin{aligned}
(\mathcal{CP})\ S\,\bar{q}_j q_i\ (\mathcal{CP})^\dagger &= \eta_S e^{i(\xi_i-\xi_j)} S\,\bar{q}_i q_j \\
(\mathcal{CP})\ S\,\bar{q}_j\gamma_5 q_i\ (\mathcal{CP})^\dagger &= -\eta_S e^{i(\xi_i-\xi_j)} S\,\bar{q}_i\gamma^5 q_j,
\end{aligned} \tag{30}$$

and Eq. (3) is transformed into

$$-\,(\mathcal{CP})\ \mathcal{L}_Y\ (\mathcal{CP})^\dagger = \eta_S S\left\{e^{i(\xi_i-\xi_j)}\bar{q}_i\left(a_{\bar{j}i} - ib_{\bar{j}i}\gamma_5\right) q_j + e^{i(\xi_j-\xi_i)}\bar{q}_j\left(a^*_{\bar{j}i} - ib^*_{\bar{j}i}\gamma_5\right) q_i\right\} + \cdots \tag{31}$$

For CP conservation to hold, the first term of Eq. (3) must equal the second term of Eq. (31), leading to

$$\begin{aligned}
a_{\bar{j}i} &= \eta_S a^*_{\bar{j}i} e^{i(\xi_j-\xi_i)}, \\
b_{\bar{j}i} &= -\eta_S b^*_{\bar{j}i} e^{i(\xi_j-\xi_i)}.
\end{aligned} \tag{32}$$

Of course, the spurious phase $(\xi_j - \xi_i)$ can be chosen to make either equation hold. This is a reflection of the known fact that a term by itself cannot lead to CP violation; one needs always the beating of two terms. However, these equations taken together mean that CP conservation implies

$$a_{\bar{j}i} b^*_{\bar{j}i} = -\left(a_{\bar{j}i} b^*_{\bar{j}i}\right)^*, \tag{33}$$

i.e. $\mathrm{Re}\left(a_{\bar{j}i} b^*_{\bar{j}i}\right) = 0$, which does not depend on the spurious phases. This is a rephasing independent sign of CP conservation. Conversely,

$$\mathrm{Re}\left(a_{\bar{j}i} b^*_{\bar{j}i}\right) \neq 0 \implies \text{CP Violation} \quad (i \neq j). \tag{34}$$

Notice the curious possibility that one could have CP conservation with $a_{\bar{j}i} b^*_{\bar{j}i} \neq 0$ as long as the two couplings were relatively imaginary. We know of no model for which this is a compulsory feature, but the possibility should be kept in mind. Of course, since hermiticity of the Lagrangian requires the diagonal couplings to be real,

$$a_{\bar{i}i} b_{\bar{i}i} \neq 0 \implies \text{CP Violation} \quad (\text{diagonal}). \tag{35}$$

A similar analysis for the parity transformation would lead to

$$a_{\bar{j}i}b^*_{\bar{j}i} \neq 0 \implies \text{P Violation}, \tag{36}$$

regardless of $i = j$ or $i \neq j$.

E. Self-cancelation in BGL models

We have mentioned that there are models where the corresponding matrix elements of X^d_+ and X^d_- have a common phase. One such example is provided by a model proposed by Branco, Grimus, and Lavoura, known as the BGL model [23, 24]. The model was constructed to obviate constraints on FCNSI by relating the matrices N_u or N_d with off-diagonal CKM matrix elements, which are known to be small. As shown in Ref. [25] under some assumptions, BGL models provide the only possible implementation in 2HDMs of a relation between FCNSI and the CKM matrix which uses abelian symmetries. There are six such models in the quark sector[4]. Three models, known as up models (types u, c, and t), have a diagonal N_u and a non diagonal N_d. Three models, known as down models (types d, s, and b), have a diagonal N_d and a non diagonal N_u.

1. *Up models*

After some calculations, we find for the type t model

$$N_u = \begin{pmatrix} m_u t_\beta & 0 & 0 \\ 0 & m_c t_\beta & 0 \\ 0 & 0 & -m_t t_\beta^{-1} \end{pmatrix} \qquad X^u_+ = N_u, \quad X^u_- = 0, \tag{37}$$

$$N_d = \begin{pmatrix} m_d\left[(1-|V_{td}|^2)t_\beta - |V_{td}|^2 t_\beta^{-1}\right] & -m_s(t_\beta + t_\beta^{-1})V_{ts}V^*_{td} & -m_b(t_\beta + t_\beta^{-1})V_{tb}V^*_{td} \\ -m_d(t_\beta + t_\beta^{-1})V_{td}V^*_{ts} & m_s\left[(1-|V_{ts}|^2)t_\beta - |V_{ts}|^2 t_\beta^{-1}\right] & -m_b(t_\beta + t_\beta^{-1})V_{tb}V^*_{ts} \\ -m_d(t_\beta + t_\beta^{-1})V_{td}V^*_{tb} & -m_s(t_\beta + t_\beta^{-1})V_{ts}V^*_{tb} & m_b\left[(1-|V_{tb}|^2)t_\beta - |V_{tb}|^2 t_\beta^{-1}\right] \end{pmatrix}, \tag{38}$$

$$X^d_+ = \begin{pmatrix} m_d\left[(1-|V_{td}|^2)t_\beta - |V_{td}|^2 t_\beta^{-1}\right] & -\frac{m_s+m_d}{2}(t_\beta + t_\beta^{-1})V_{ts}V^*_{td} & -\frac{m_b+m_d}{2}(t_\beta + t_\beta^{-1})V_{tb}V^*_{td} \\ -\frac{m_d+m_s}{2}(t_\beta + t_\beta^{-1})V_{td}V^*_{ts} & m_s\left[(1-|V_{ts}|^2)t_\beta - |V_{ts}|^2 t_\beta^{-1}\right] & -\frac{m_b+m_s}{2}(t_\beta + t_\beta^{-1})V_{tb}V^*_{ts} \\ -\frac{m_d+m_b}{2}(t_\beta + t_\beta^{-1})V_{td}V^*_{tb} & -\frac{m_s+m_b}{2}(t_\beta + t_\beta^{-1})V_{ts}V^*_{tb} & m_b\left[(1-|V_{tb}|^2)t_\beta - |V_{tb}|^2 t_\beta^{-1}\right] \end{pmatrix}, \tag{39}$$

$$X^d_- = \begin{pmatrix} 0 & -\frac{m_s-m_d}{2}(t_\beta + t_\beta^{-1})V_{ts}V^*_{td} & -\frac{m_b-m_d}{2}(t_\beta + t_\beta^{-1})V_{tb}V^*_{td} \\ \frac{m_s-m_d}{2}(t_\beta + t_\beta^{-1})V_{td}V^*_{ts} & 0 & -\frac{m_b-m_s}{2}(t_\beta + t_\beta^{-1})V_{tb}V^*_{ts} \\ \frac{m_b-m_d}{2}(t_\beta + t_\beta^{-1})V_{td}V^*_{tb} & \frac{m_b-m_s}{2}(t_\beta + t_\beta^{-1})V_{ts}V^*_{tb} & 0 \end{pmatrix}, \tag{40}$$

The matrices X^α_+ are hermitian, while X^α_- are anti-hermitian. Moreover, as announced, $\left(X^d_+\right)_{\bar{j}i}$ has the same phase as $\left(X^d_-\right)_{\bar{j}i}$. Notice that the $(t_\beta + t_\beta^{-1})$ prefactor in the off diagonal terms can make the FCNSI large for sufficiently large values of $\tan\beta$.

The matrix N_d is highly hierarchical, both due to the masses and due to the CKM matrix elements. Concentrating on the off-diagonal matrix elements, and taking out the $(t_\beta + t_\beta^{-1})$ prefactor, the orders of magnitude for X^d_+ and X^d_- in the t type model are

$$X^d_\pm \sim \begin{pmatrix} \text{x} & m_s\lambda^5 & m_b\lambda^3 \\ \text{x} & \text{x} & m_b\lambda^2 \\ \text{x} & \text{x} & \text{x} \end{pmatrix} \quad (t \text{ type}), \tag{41}$$

[4] These branch into more possibilities once one takes the leptonic sector into account [26].

where λ is the expansion parameter in the Wolfenstein parametrization of the CKM matrix [27]. We show only the 12, 13, and 23 elements because we are focusing on flavour violating transitions and because the transposed elements are of the same order of magnitude. Thus, in the t type model, the largest contribution would occur in the B_s system. The only difference in the c type model is that the CKM combinations $V_{\alpha i}V^*_{\alpha j}$ with $\alpha = t$ get changed into $V_{\alpha i}V^*_{\alpha j}$ with $\alpha = c$, and similarly for the u type model. Thus,

$$X^d_\pm \sim \begin{pmatrix} \mathrm{x} & m_s\lambda & m_b\lambda^3 \\ \mathrm{x} & \mathrm{x} & m_b\lambda^2 \\ \mathrm{x} & \mathrm{x} & \mathrm{x} \end{pmatrix} \quad (c \text{ type}), \tag{42}$$

$$X^d_\pm \sim \begin{pmatrix} \mathrm{x} & m_s\lambda & m_b\lambda^3 \\ \mathrm{x} & \mathrm{x} & m_b\lambda^4 \\ \mathrm{x} & \mathrm{x} & \mathrm{x} \end{pmatrix} \quad (u \text{ type}). \tag{43}$$

Eqs. (41)-(43) can be used by model builders to increase some FCNSI of interest and suppress others.

Let us focus again on the t type model. In this model

$$\left|\frac{X^d_+}{X^d_-}\right|^2 = \left(\frac{m_{q_2}+m_{q_1}}{m_{q_2}-m_{q_1}}\right)^2 > 1. \tag{44}$$

Since we see from Table I that $K^P_b > K^P_a$, the cancelation in Eq. (28) is not possible, while, due to the hierarchical mass structure of the different quark families, the cancelation in Eq. (27) is only partial, as we see from Table III. Thus, although the relative minus signs in Table II indicate some self-cancelation, in the BGL models this cancelation

Meson system	K^0–$\bar{K}^0$	B^0_d–$\bar{B}^0_d$	B^0_s–$\bar{B}^0_s$
K^P_b/K^P_a	10.6	7.1 [2.9]	7.1 [3.2]
$(m_{q_2}+m_{q_1})^2/(m_{q_2}-m_{q_1})^2$	1.2	1.0	1.1

TABLE III: Comparison of the ratios needed for the self-cancelation in Eq. (27). The numbers are obtained from Table I, except those whithin [], which are obtained from Eq. (8) and the lattice simulation of Ref. [18].

is not complete because the ratios os masses are not enough to offset the ratios of hadronic matrix elements. We note that the cancelation is more effective when the matrix elements are estimated with the lattice results of Ref. [18], then when they are estimated in the vacuum insertion approximation. We conclude that this mechanism must be taken into account in the experimental search for the features of a generic 2HDM. Indeed, as this example shows, an accidental cancelation is quite likely and should not be ruled out a priori.

2. Down models

After some calculations, we find for the type b model

$$N_u = \begin{pmatrix} m_u\left[(1-|V_{ub}|^2)t_\beta - |V_{ub}|^2 t_\beta^{-1}\right] & -m_c(t_\beta + t_\beta^{-1})V_{cb}V^*_{ub} & -m_t(t_\beta + t_\beta^{-1})V_{tb}V^*_{ub} \\ -m_u(t_\beta + t_\beta^{-1})V_{ub}V^*_{cb} & m_c\left[(1-|V_{cb}|^2)t_\beta - |V_{cb}|^2 t_\beta^{-1}\right] & -m_t(t_\beta + t_\beta^{-1})V_{tb}V^*_{cb} \\ -m_u(t_\beta + t_\beta^{-1})V_{ub}V^*_{tb} & -m_c(t_\beta + t_\beta^{-1})V_{cb}V^*_{tb} & m_t\left[(1-|V_{tb}|^2)t_\beta - |V_{tb}|^2 t_\beta^{-1}\right] \end{pmatrix} \tag{45}$$

$$X^u_+ = \begin{pmatrix} m_u\left[(1-|V_{ub}|^2)t_\beta - |V_{ub}|^2 t_\beta^{-1}\right] & -\frac{m_u+m_c}{2}(t_\beta + t_\beta^{-1})V_{cb}V^*_{ub} & -\frac{m_u+m_t}{2}(t_\beta + t_\beta^{-1})V_{tb}V^*_{ub} \\ -\frac{m_u+m_c}{2}(t_\beta + t_\beta^{-1})V_{ub}V^*_{cb} & m_c\left[(1-|V_{cb}|^2)t_\beta - |V_{cb}|^2 t_\beta^{-1}\right] & -\frac{m_c+m_t}{2}(t_\beta + t_\beta^{-1})V_{tb}V^*_{cb} \\ -\frac{m_u+m_t}{2}(t_\beta + t_\beta^{-1})V_{ub}V^*_{tb} & -\frac{m_c+m_t}{2}(t_\beta + t_\beta^{-1})V_{cb}V^*_{tb} & m_t\left[(1-|V_{tb}|^2)t_\beta - |V_{tb}|^2 t_\beta^{-1}\right] \end{pmatrix} \tag{46}$$

$$X^u_- = \begin{pmatrix} 0 & -\frac{m_c-m_u}{2}(t_\beta + t_\beta^{-1})V_{cb}V^*_{ub} & -\frac{m_t-m_u}{2}(t_\beta + t_\beta^{-1})V_{tb}V^*_{ub} \\ \frac{m_c-m_u}{2}(t_\beta + t_\beta^{-1})V_{ub}V^*_{cb} & 0 & -\frac{m_t-m_c}{2}(t_\beta + t_\beta^{-1})V_{tb}V^*_{cb} \\ \frac{m_t-m_u}{2}(t_\beta + t_\beta^{-1})V_{ub}V^*_{tb} & \frac{m_t-m_c}{2}(t_\beta + t_\beta^{-1})V_{cb}V^*_{tb} & 0 \end{pmatrix} \tag{47}$$

$$N_d = \begin{pmatrix} m_d t_\beta & 0 & 0 \\ 0 & m_s t_\beta & 0 \\ 0 & 0 & -m_b t_\beta^{-1} \end{pmatrix}, \qquad X_+^d = N_d, \quad X_-^d = 0. \tag{48}$$

In terms of orders of magnitude, we have

$$X_\pm^u \sim \begin{pmatrix} \mathrm{x} & m_c\lambda^5 & m_t\lambda^3 \\ \mathrm{x} & \mathrm{x} & m_t\lambda^2 \\ \mathrm{x} & \mathrm{x} & \mathrm{x} \end{pmatrix} \quad (b \text{ type}), \tag{49}$$

$$X_\pm^u \sim \begin{pmatrix} \mathrm{x} & m_c\lambda & m_t\lambda^3 \\ \mathrm{x} & \mathrm{x} & m_t\lambda^2 \\ \mathrm{x} & \mathrm{x} & \mathrm{x} \end{pmatrix} \quad (s \text{ type}), \tag{50}$$

$$X_\pm^u \sim \begin{pmatrix} \mathrm{x} & m_c\lambda & m_t\lambda^3 \\ \mathrm{x} & \mathrm{x} & m_t\lambda^4 \\ \mathrm{x} & \mathrm{x} & \mathrm{x} \end{pmatrix} \quad (d \text{ type}). \tag{51}$$

Notice that the orders of magnitude of the CKM coefficients in Eqs. (49)-(51) reproduce those in Eqs. (41)-(43), respectively; the masses are, obviously, different. Again, this is not enough to make the self-cancelation fully effective for BGL models in the D system.

III. FCNSI-INDUCED HIGGS PRODUCTION AT THE LHC

The Lagrangian in Eq. (3) induces $pp \to S$ direct production with $\bar{q}_j$ and q_i as partons (and also, with partons $\bar{q}_i$ and q_j). At leading order in the narrow width approximation, we find

$$\sigma\left[pp(\bar{q}_j q_i) \to S)\right] = 2\,\frac{\pi}{8N_c E^2}\left(|a_{\bar{j}i}|^2 + |b_{\bar{j}i}|^2\right) I_{\bar{q}_j q_i}\,, \tag{52}$$

where

$$I_{\bar{q}_j q_i} = \int_{x_0}^1 dx\, f_{\bar{q}_j}^p(x,Q^2) f_{q_i}^p(x_0/x,Q^2)\frac{1}{x}\,. \tag{53}$$

A factor of two was explicitly included in Eq. (52) (due to the fact that a given parton can come with equal probability from either proton – things would be different in a $p\bar{p}$ collision), N_c is the number of colours, E is the energy of the colliding proton, f_X^p are the relevant parton distribution functions (PDFs), and

$$x_0 = \frac{m_S^2}{4E^2}. \tag{54}$$

Notice that

$$\frac{\sigma\left[pp(\bar{q}_i q_j) \to S)\right]}{\sigma\left[pp(\bar{q}_j q_i) \to S)\right]} = \frac{I_{\bar{q}_i q_j}}{I_{\bar{q}_j q_i}} \tag{55}$$

is not unity, since, in general $f_{\bar{q}_i}^p \neq f_{\bar{q}_j}^p$ and $f_{q_j}^p \neq f_{q_i}^p$. For instances, although Eq. (4) implies that $|a_{\bar{c}u}| = |a_{\bar{u}c}|$ and $|b_{\bar{c}u}| = |b_{\bar{u}c}|$, $\sigma\left[pp(\bar{c}u) \to S)\right]$ does not equal $\sigma\left[pp(\bar{u}c) \to S)\right]$.

In order to estimate the change obtained in going from LO to NNLO, we use SusHi (version 1.5.0) [28] with the factorization and running scales $\mu_F = \mu_R = m_S/4$ [29–36] in order to find

$$R(m_S) = \frac{\sigma\left[pp(\bar{b}b) \to S)\right]_{\mathrm{NNLO}}^{\mathrm{SusHi}}}{\sigma\left[pp(\bar{b}b) \to S)\right]_{\mathrm{LO}}}. \tag{56}$$

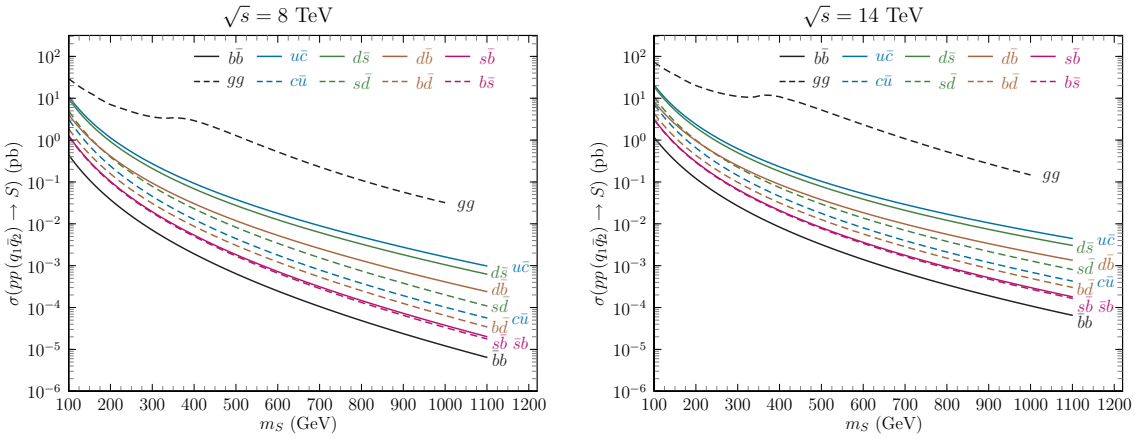

FIG. 1: Cross section for S production in pp collisions at 8TeV-Left panel (14TeV-Right panel) through the $q_i q_j$ partons indicated, assuming that they couple as the SM $b\bar{b}$. For reference, we show also the cross-section for glue-glue production.

For each scalar mass m_S, we use $R(m_S)$ as a universal rescaling factor for all our production cross sections, thus taking into account the major factors appearing in going from LO to NNLO. To see the effect of the different PDFs, we show in Fig. 1 the cross sections calculated as a function of m_S, assuming that all couplings coincide with the SM $b\bar{b}$ couplings $a_{\bar{b}b} = m_b/v$ and $b_{\bar{b}b} = 0$. Also shown is the SM gluon-gluon fusion production cross section, typically two to three orders of magnitude larger than the SM $b\bar{b}$. Of course, as seen in Fig. 1, if the FCNSI couplings were all equal to m_b/v, then the fact that the u and d PDFs in the proton are larger than all others, would mean that the productions through $u\bar{c}$, $d\bar{s}$, and $d\bar{b}$ would be the largest. We see also that there is a very small difference between $s\bar{b}$ and $b\bar{s}$.

Since the bounds from leptonic decays depend also on the details of the leptonic sector, we will concentrate on the bounds from $P^0 - \overline{P^0}$ mixing. Let us decide that the scalar contribution to $|M_{21}|$ in Eq. (5) is a fraction η of the total contribution, including also the SM box diagram:

$$\left|M_{12}^S\right| = \eta \left|M_{12}\right| . \tag{57}$$

In the notation of the CKMfitter group [14, 15],

$$M_{12}^{\rm sm} + M_{12}^S = M_{12} = M_{12}^{\rm sm}\,\Delta. \tag{58}$$

Thus

$$\eta = \left|\frac{\Delta - 1}{\Delta}\right|. \tag{59}$$

In the notation of the UTfit collaboration, $\Delta = Ce^{2i\phi}$ [16]. For the B systems, a very conservative guess would be 10%. In the K and D systems, the long distance contributions have a large uncertainty which could easily hide a scalar contributions amounting to 200% of the SM contributions, but with the opposite sign.

A. Pure scalar or pseudoscalar couplings

We start by assuming that the scalar S is either a pure scalar ($b = 0$) or a pure pseudoscalar ($a = 0$). From Eqs. (5), (6), and (57), we find the upper limit

$$|c^{\rm max}| = \sqrt{\frac{12}{K_c^P}\frac{\eta\,\Delta m_P}{m_P}}\;\frac{m_S}{f_P}, \tag{60}$$

where $c = a, b$, and which depends linearly on m_S, as announced in Eq. (1).

We have mentioned in connection with Table I and Eq. (7) that the pseudoscalar matrix elements K_b^p are always larger than their scalar counterparts K_a^p (at least in the vacuum insertion approximation and the lattice estimate of Ref. [18] used here). This means that the maximum allowed values for the pseudoscalar couplings (b) will always be

Meson system	K^0–$\bar{K}^0$	B_d^0–$\bar{B}_d^0$	B_s^0–$\bar{B}_s^0$	D^0–$\bar{D}^0$
$\lvert a^{\max}\rvert$ (125GeV)	4.58×10^{-5}	1.13×10^{-4}	5.61×10^{-4}	6.28×10^{-5}
$\lvert b^{\max}\rvert$ (125GeV)	1.41×10^{-5}	4.24×10^{-5}	2.11×10^{-4}	2.25×10^{-5}
$\lvert a^{\max}\rvert$ (1TeV)	3.66×10^{-4}	9.02×10^{-4}	4.49×10^{-3}	5.03×10^{-4}
$\lvert b^{\max}\rvert$ (1TeV)	1.12×10^{-4}	3.39×10^{-4}	1.68×10^{-3}	1.80×10^{-4}

TABLE IV: Meson mixing constraints on couplings for $m_S = 125$ GeV and for $m_S = 1$ TeV. For comparison, the $b\bar{b}S$ coupling is $\frac{m_b}{v} = 1.138 \times 10^{-2}$, for a running mass of $m_b = 2.8$ GeV.

smaller than the corresponding scalar couplings (a) by a factor of roughly 3 ($\sqrt{3}$ using Ref. [18]). Of course, since we are using estimates of these matrix elements, all results must be taken as indicative rather than tight constraints. For $m_h = 125$GeV ($m_h = 1$TeV), we find the maximum values shown in Table IV. For comparison, the $b\bar{b}h$ coupling is $c_{Sbb}^{\rm sm} = \frac{m_b}{v} = 1.138 \times 10^{-2}$, for a running mass of $m_b = 2.8$ GeV. The best case occurs in the B_s^0–$\bar{B}_s^0$ system with scalar coupling, but still

$$\frac{|a_{bs}^{\max}|}{c_{Sbb}^{\rm sm}} = 0.05 \;\; (125\text{GeV}), \qquad \frac{|a_{bs}^{\max}|}{c_{Sbb}^{\rm sm}} = 0.4 \;\; (1\text{TeV}). \tag{61}$$

Fig. 2 shows the cross sections for production through $q_1\bar{q}_2$ and $q_2\bar{q}_1$ obtained when the couplings are pure scalar ($b = 0$), having the largest possible magnitude consistent with meson mixings. Recall that the value for $|a^{\max}|$ increases with m_S. Similarly, Fig. 3 shows the cross sections for production through $q_1\bar{q}_2$ and $q_2\bar{q}_1$ obtained when the

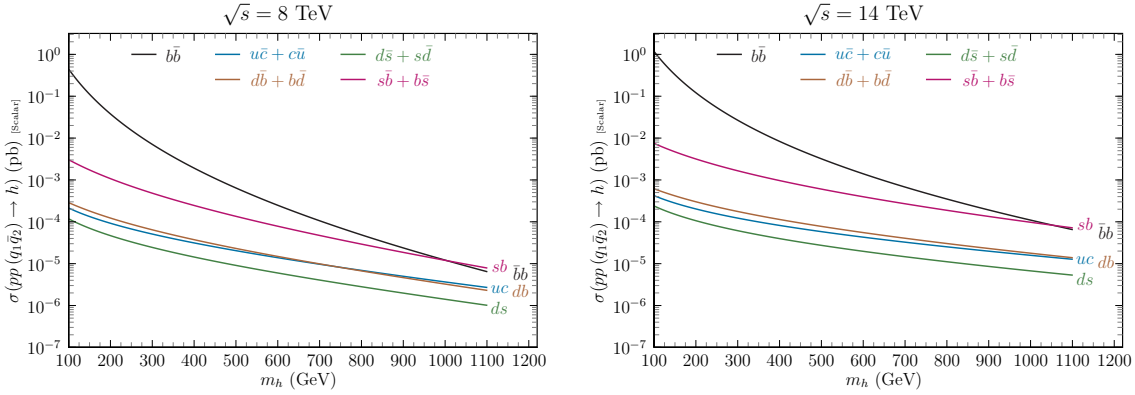

FIG. 2: Sum of the cross sections $\sigma(pp\,(q_1\bar{q}_2) \to S) + \sigma(pp\,(q_2\bar{q}_1) \to S)$ for the maximal values of the pure scalar couplings consistent with meson mixings, for 8TeV-Left panel (14TeV-Right panel).

couplings are pure pseudoscalar ($a = 0$), having the largest possible magnitude consistent with meson mixings. Now one needs the value for $|b^{\max}|$, which also increases with m_S.

We stress that our concern here is not on exact values. Our values for η and the hadronic matrix elements are taken just to illustrate the order of the effects. As we will see in the nest section, the mechanism of self-cancelation can enhance the allowed effects and, thus, it should be taken as a possibility in phenomenological searches.

B. Self-cancelations and fine tuning

We now inquire how much fine tuning might one need in the self-cancelation, in order that $\sigma\left[pp(\bar{q}_j q_i) \to S)\right]$ might be a relevant portion of the production mechanism. For definiteness, we concentrate on the B_s system. For each value of m_S, we define

$$\begin{aligned} r &= \frac{\sigma\left[pp(\bar{b}s + \bar{s}b) \to S)\right]_{\rm NNLO}}{\sigma\left[pp(gg) \to S)\right]_{\rm SM}} = \frac{R\,\sigma\left[pp(\bar{b}s + \bar{s}b) \to S)\right]_{\rm LO}}{\sigma\left[pp(gg) \to S)\right]_{\rm SM}} \\ &= \frac{\pi R}{4N_c E^2}\left(|a_{\bar{b}s}|^2 + |b_{\bar{b}s}|^2\right)\frac{I_{\bar{b}s} + I_{\bar{s}b}}{\sigma\left[pp(gg) \to S)\right]_{\rm SM}}. \end{aligned} \tag{62}$$

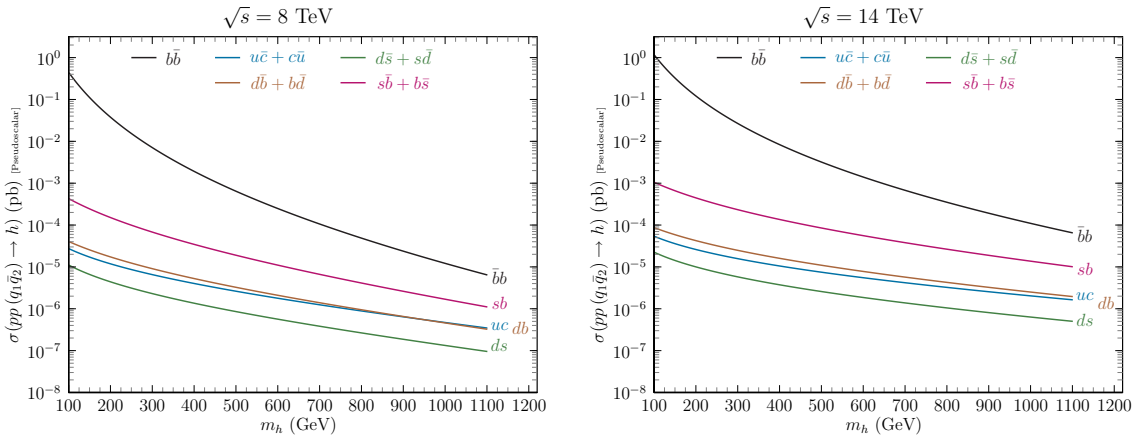

FIG. 3: Sum of the cross sections $\sigma(pp\,(q_1\bar{q}_2) \to S) + \sigma(pp\,(q_2\bar{q}_1) \to S)$ for the maximal values of the pure pseudoscalar couplings consistent with meson mixings, for 8TeV-Left panel (14TeV-Right panel).

In many circumstances $\sigma\,[pp(gg) \to S)]_{\rm SM}$ is not an appropriate reference value, because the coupling to the top quark (needed for the top quark triangle diagram driving the production through gluon-gluon fusion in the SM) is suppressed for extra scalars. As an example, let us consider the type t model of Eq. (37). We have $X_- = 0$ and the $(X_+)_{tt}$ coupling is suppressed by t_β^{-1} for large t_β. From Eqs. (26) we see that the first piece in the $A_{tt}^{u,H}$ coupling is proportional to $m_t c_{\alpha-\beta}$. The current LHC bounds on decays into vector bosons constrain $s^2_{\alpha-\beta}$ to lie within 20% of the SM value 1. Assuming the central value remains unity, Run 2 at the LHC should improve this bound to within 5%. As a result, the gluon-gluon fusion production of H would be down with respect to the SM by roughly 0.05. Under these circumstances, the natural reference value for the gluon-gluon fusion production value would be 5% of the SM value. This can be accounted for by taking as the natural value $r = 0.05$.

For a given value of r (say, 10%), Eq. (62) gives a limit on $|a_{\bar{b}s}^{\rm max}|^2 + |b_{\bar{b}s}^{\rm max}|^2$. Of course, these values will be much larger than those obtained from Eq. (60). We would now like these values of $|a_{\bar{b}s}^{\rm max}|$ and $|b_{\bar{b}s}^{\rm max}|$ to survive the Δm_{B_s} bound through the self-cancelation mechanism. We define the proportion of fine tuning required by

$$\begin{aligned} p_{\rm FT} &= \frac{|a_{\bar{b}s}^2 + b_{\bar{b}s}^2\, K_b^{B_s}/K_a^{B_s}|}{|a_{\bar{b}s}|^2 + |b_{\bar{b}s}|^2} \\ &= \frac{\eta\,\Delta m_{B_s}}{K_a^{B_s}\, m_{B_s}} \left(\frac{m_S}{f_{B_s}}\right)^2 \frac{\pi R\,(I_{\bar{b}s} + I_{\bar{s}b})}{E^2\, r\sigma\,[pp(gg) \to S)]_{\rm SM}}, \end{aligned} \tag{63}$$

where we have used Eqs. (5), (6), (57), and (62). For example, $p_{\rm FT} = 0.01$ implies a fine tuning within 1%. A larger value of $p_{\rm FT}$ implies a lower fine tuning. Of course, the smaller the value chosen for r, the smaller the fine tuning (larger $p_{\rm FT}$). This is clearly seen in Fig. 4, showing $p_{\rm FT}$ as a function of m_S for $r = 1$, $r = 0.1$, and $r = 0.05$. Consider, for example, a situation similar to that in the type t model, where the natural gluon-gluon production corresponds to $r = 0.05$, and take $m_S = 800$GeV. We learn from Fig. 4 that for bs production to be equal to the gluon-gluon production requires a fine tuning in the self-cancelation within 1%. But this means that a reasonable self-cancelation within 10%, would imply a bs production to contribute around 10% of the total production.

Notice that, in a generic model, the couplings of the spin 0 particle to bs, bd, and ds are independent. Thus, in a model independent search, each neutral meson system should be considered independently. However, in many models the couplings in each sector could have specific relations, as illustrated above in the BGL system. For definiteness, let us assume that the scalar S couples like one of the scalars in the type t model. According to Table II, the couplings

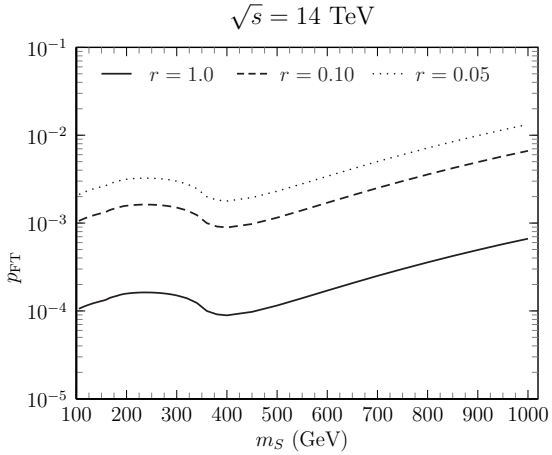

FIG. 4: $p_{\rm FT}$ as a function of m_S for $r = 1$ (solid line), $r = 0.1$ (dashed), and $r = 0.05$ (dotted).

go like $\left(X^d_\pm\right)^2_{\bar{j}i}$, which scale like the square of the entries of the matrix in Eq. (41). Namely, for the type t model[5]:

$$\begin{aligned} K &: m_s^2\, V_{ts}^2 V_{td}^{2\,*}, \\ B_d &: m_b^2\, V_{tb}^2 V_{td}^{2\,*}, \\ B_s &: m_b^2\, V_{tb}^2 V_{ts}^{2\,*}. \end{aligned} \tag{64}$$

The key point is that both the scalar (a) and pseudoscalar (b) coefficients scale in the same way. From Eqs. (5)-(6), we get

$$\frac{\Delta m_{B_s}}{\Delta m_{B_d}} = \frac{f_{B_s}^2\, m_{B_s}}{f_{B_d}^2\, m_{B_d}} \frac{\left[a_{\bar{b}s}^2 K_a^{B_s} + b_{\bar{b}s}^2 K_b^{B_s}\right]}{\left[a_{\bar{b}d}^2 K_a^{B_d} + b_{\bar{b}d}^2 K_b^{B_d}\right]}. \tag{65}$$

Since K_b/K_a is almost the same in the B_d and B_s systems and since, for each system, a and b scale in the same way, we expect that a 10% self-cancelation in the B_s system will also imply a 10% self-cancelation in the B_d system. For the kaon system, besides the SM-like CKM rescaling, there is an m_s^2/m_b^2 suppression. Indeed, taking

$$c_{\bar{s}d} \sim \frac{m_s^2\, \lambda^{10}}{m_b^2\, \lambda^4} c_{\bar{b}s} \tag{66}$$

for $c = a, b$, we find,

$$\Delta m_K = \left(\frac{m_s}{m_b}\lambda^3\right)^2 \frac{\left[a_{\bar{b}s}^2 K_a^K + b_{\bar{b}s}^2 K_b^K\right]}{\left[a_{\bar{b}s}^2 K_a^{B_s} + b_{\bar{b}s}^2 K_b^{B_s}\right]} \frac{f_K^2\, m_K}{f_{B_s}^2\, m_{B_s}} \Delta m_{B_s}. \tag{67}$$

This means that a 10% self-cancelation in B_s implies very small contributions to the mixing in the kaon system.

Should it turn out that the self-cancelation mechanism is particularly effective (such that the FCNSI induced scalar production is a relevant percentage of the with gluon-gluon production), then one must look to other FCNSI effects for further constraints. As mentioned, decays of the type $P^0 \to \ell^+\ell^-$ are only relevant if the scalar has a relevant coupling to $\ell^+\ell^-$. In theories where this coupling is free, it could even vanish and no addition constraint arises. But in some theories this coupling is fixed by other quantities (such as masses and, possibly, elements of the leptonic mixing matrix), and they must be taken into account. For completeness, the appendix includes the relevant formulae.

Finally, if the FCNSI couplings are large, they could induce $S \to q_i \bar{q}_j$ decays. Using the expressions in the appendix and the values of $a^{\max}$ and $b^{\max}$ in Table IV for $m_S = 125$GeV, we find that the effects for $S \to \bar{b}s + \bar{s}b$ are less

[5] Notice that, in the type t mode, the CKM coefficients in Eqs. (64) coincide with the coefficients that arise from the respective SM box diagrams. This means that the CKM multiplicative factor in the new contributions scale from system to system in accordance with experiment.

than a few percent of the total width, and completely irrelevant for the other FCNSI decays. As seen in Fig. 2, for a sufficiently large m_S the maximum scalar partial width of $S \to \bar{b}s + \bar{s}b$ could exceed $S \to \bar{b}b$. But for masses above ~ 135GeV, the decays into vector bosons take over. As a result, the $S \to \bar{b}s + \bar{s}b$ decay will typically be a minute fraction of the total width.

IV. CONCLUSIONS

In general, a theory with more than one neutral scalar will induce FCNSI. Because these lead to mixing in the neutral meson systems, it is customary to eliminate or suppress such contributions. Strategies in the literature range from discrete symmetries – for example, a Z_2 symmetry in 2HDMs [37, 38] –, to relation with CKM matrix elements [23], and/or large scalar masses. In this article, we highlight a further possibility, which could occur for a spin 0 state with both scalar and pseudoscalar couplings. In that case, one could have a self-cancelation between both couplings.

We explain in detail how this mechanism could occur even in models where the Higgs potential and the vacuum preserve CP. We illustrated this effect by showing the explicit couplings of the BGL models [23]. This case shows that a self-cancelation is quite natural, at least to some degree, depending on the exact values of the hadronic matrix elements. Our evaluations of this effect in the B systems are more promising using lattice estimates than using estimates with the vacuum insertion approximation.

We also investigated the possibility that such FCNSI could induce a new mechanism of scalar production at LHC. In a theory with multi Higgs we expect that FCNSI can be ignored as a production mechanism, except in two cases: for some scalar where self-cancelation is active to some accuracy; or in limiting cases where the contribution from different scalars cancel each other, as illustrated in at the end of Section II C. These effects should not be ruled out a priori.

Acknowledgments

J.P.S. is very grateful to Lincoln Wolfenstein for many discussions on the topics covered in this article, who sadly passed away recently. We are grateful to F.J. Botella, L. Lavoura, P. Pal, J. Romão, and R. Santos for discussions. This work is supported in part by the Portuguese *Fundação para a Ciência e Tecnologia* (FCT) under contract UID/FIS/00777/2013. M.N. is supported in part by FCT through a postdoctoral fellowship under PTDC/FIS-NUC/0548/2012, and through CERN/FP/123580/2011; these projects are partially funded through COMPETE, QREN, POCTI (FEDER) and EU.

[22] Some care is needed when using h and H from different sources, especially when interfering signs matter. The different definitions in the literature may be written as

$$\begin{pmatrix} \xi_H\, H \\ \xi_h\, h \end{pmatrix} = \begin{pmatrix} c_\alpha & s_\alpha \\ -s_\alpha & c_\alpha \end{pmatrix} \begin{pmatrix} \rho_1 \\ \rho_2 \end{pmatrix} \tag{68}$$

where ξ_h and ξ_H represent possible independent choices for the signs $\pm$. Here we use $\xi_h = \xi_H = +$, while, for example, Eqs. (12)-(14) of Ref [5] use $\xi_h = \xi_H = -$.

Appendix A: Further FCNSI processes

We are also interested in the decays of P^0 into two a pair of charged leptons $P^0 \to \ell^+\ell^-$. We write the couplings of the scalar into the lepton pair as

$$-\mathcal{L}_Y = S\left\{\bar{\ell}\,(a_\ell + i b_\ell \gamma_5)\,\ell\right\} + \cdots \tag{A1}$$

where a_ℓ and b_ℓ are real. We find[6]

$$\Gamma[P^0 \to \ell^+\ell^-] = \frac{1}{8\pi}\frac{m_P^5\, f_P^2}{(m_{q_j}+m_{q_i})^2\; m_S^4}\,|b_{\bar{j}i}|^2\,\beta_\ell\,\left[|a_\ell|^2\,\beta_\ell^2 + |b_\ell|^2\right], \tag{A2}$$

where

$$\beta_\ell = \sqrt{1-\frac{4m_\ell^2}{m_P^2}}, \tag{A3}$$

and the form factor f_P arises from

$$\langle 0|\bar{q}_j\gamma_5 q_i|P^0\rangle = i\frac{m_P^2}{m_{q_j}+m_{q_i}}\,f_P, \qquad \langle 0|\bar{q}_j q_i|P^0\rangle = 0. \tag{A4}$$

Notice that $a_{\bar{j}i}$ does not appear in Eq. (A2) because the pseudoscalar meson P cannot couple to the scalar component of S, as seen in the second matrix element of Eq. (A4).

[6] The $\overline{P^0} \to \ell^+\ell^-$ would seem to involve the different factor $|b_{\bar{i}j}|$, but, given Eq. (4), $|b_{\bar{i}j}| = |b_{\bar{j}i}|$.

Finally, the Lagrangian in Eq. (3) induces $h \to \bar{q}_i q_j$ decays. We find

$$\Gamma\left[S \to \bar{q}_i q_j\right] = \frac{N_c}{8\pi\, m_S^3} \sqrt{\alpha_+ \alpha_-}\left[|a_{\bar{j}i}|^2 \alpha_+ + |b_{\bar{j}i}|^2 \alpha_-\right], \tag{A5}$$

where

$$\alpha_\pm = m_S^2 - \left(m_{q_i} \pm m_{q_j}\right)^2. \tag{A6}$$
